Compromise

Prediction-based lossless compression

Sample-based predictions

- Each sample predicted from its recent history.
 - a) Single prediction type \rightarrow encode only residuals (and a few starting samples).
 - b) Different prediction types \rightarrow encode types (with short codes) and residuals.

Feature-based predictions

- The same prediction type for the whole segment.
- Prediction (feature) interpolates (approximates) the segment.
- Each segment coded by:
 - Feature type (except there is a single type)
 - Feature parameters (segment borders + interpolation function)
 - Residuals.

Feature-based predictions

- Feature parameters coding = lossy compression of a segment
- All features \rightarrow lossy compression of the whole input stream
- Is this good (useful)? Yes, if:
 - Compact representation of (all) features.
 - Small residuals mostly (low entropy, good "compressibility").
 - Note that features and residuals are losslessly compressed afterwards.

Feature-based predictions (our experience)

 Segments (intervals in 1D audio) obtained by identification of distinct extremes (apart enough from each other).

Feature-based predictions (our experience)

- Feature types:
 - Line Segment
 - Average
 - Polyline
 - RLE
 - Verbatim

FERI Faculty of Electrical Engineering and Computer Science

Feature-based predictions (our experience)

- ▶ 7-11% worse than Monkey's audio (APE).
- ▶ Better than in early versions, but ... 😕
- ► Feature representation = lossy compression → why not use some "good" domain-dependent lossy compression instead?
- ▶ OGG Vorbis lossy compression → only 1–2% worse than APE.
 ◎ We even found a winning example.
- Goal: beat APE. No results today. Just concepts and discussion.

Means to achieve the goal

- OGG is not optimal in all cases.
- OGG is flexible but:
 - \circ Low quality \rightarrow small OGG file; big residuals, too much space for them.
 - High quality \rightarrow bigger OGG file; small residuals, less space for them.
 - As written, 1–2% missing in both cases, with few irrelevant exceptions.
- On the other hand, segment features might interpolate data perfectly or catastrophically, depending on data.
- A combination: determine which segments to treat as segment features and which to compress with OGG.
 - Do not compress each "OGG segment" into a separate file, but buffer the data and run a single OGG compression afterwards.

Means to achieve the goal

- Besides hybrid OGG-feature compression:
 - by refreshing the repertoire of feature types,
 - by a new concept of feature selection (segmentation),
 - by different entropy coding
 - Currently, residuals compressed to APE after reconstruction from OGG. Not optimal, even Rar and Zip are better with small residuals (exactly when features beat OGG!).
 - Try our implementations of BASC, AC, Deflate, Rice coding, ..., with/without MTF, BWT, MwI).

Preliminaries

- ▶ Input stream (channel) \rightarrow blocks. Default length 0.1s.
- Default input: CD Audio (PCM, Stereo, 44,1 kHz, 16-bit).
- Block → intervals (segments) between pairs of successive distinct extrema (min. and max., or max. and min.).
- Optional preprocessing
 - PCM \rightarrow DPCM, DDPCM (or other simple predictions).
 - \circ Left and right channel \rightarrow Central and side channel.

Blocks (4410 samples, 0.1 seconds)

Segmentation

- OGG better with high frequencies (short intervals between distinct extremes).
- New feature Restore introduced.
 - Based on parabolla through tree consecutive samples.
 - $y = a^*x^2 + b^*x + c$ through (x_i, y_i) , (x_{i+1}, y_{i+1}) , (x_{i+2}, y_{i+2}) :
 - $\circ \ a = (y_i 2y_{i+1} + y_{i+2})/2$
 - $b = y_{i+1} y_i a \cdot (x_i + x_{i+1})$
 - $\circ \ c = y_i a \cdot x_i^2 b \cdot x_i$
- It provides a unified treatment of parabolas, line segments and RLE.
- Only Polyline will be used next to OGG (for Verbatim) and Restore.

New feature Restore

Unified treatment of parabolas, line segments and RLE.

Parabola:	$a \neq 0$
Non-horizontal line segment:	$a = 0, b \neq 0$
Horizontal line segment (RLE):	a = b = 0

- After determining a, b and c for a triplet of consecutive samples, the algorithm extrapolates the parabola (or line segment) until the error becomes too large.
 - Such greedy approach is not optimal and has a potential for improvements.
- Lossless, near-lossless and lossy mode in the same framework.

Usability test

- Before implementing the new feature Restore, we analyzed on 20 songs, how often parabolas, line segments and RLE are met in practice.
- Percentage of samples included in Restore intervals below 1%.
- However, this feature can be used as a good prediction, even where errors are above zero. In general, it produces low errors (residuals).
- Lossless, near-lossless and lossy mode in the same framework.
- With residual treshold 256 or 512 (9 or 10 bits for an uncompressed residual) and minimal interval length 20, about 5% samples were addressed by Restore.

New concept (to be tested soon)

- 1. Identify intervals Restore.
- 2. Identify intervals Polyline between consecutive Restore pairs.
- 3. Compress features and residuals with the selected method (BASC, AC, Rice, Deflate, with/without MTF, BWT, MwI).
- 4. Other data (blocks or segments) are buffered and stored as OGG Vorbis. Of course, residuals are stored for this segments as well.

NOTE: Instead of OGG Vorbis, ANN (autoencoder) can be used, but this requires an intensive training (perhaps in new project).
